Pollens from diverse grass plants are main contributors to seasonal inhalant allergies worldwide. Grass group 1 and 5 allergens represent highly cross-reactive and potent major allergens, group 5 present only in temperate climate grasses (Pooidae). Depending on climate and region, global sensitization rates to grass pollen extracts vary between 1% to 30% of the general population. Strong evidence supports specific immunotherapy with grass pollen extracts.

**Botanical Relationship**
Grasses are ubiquitous plants in most parts of the world. The grass family (Poaceae) includes >600 genera and >11,000 recognized species with a wide distribution. Over 95% of allergy-relevant grass species belong to three sub-families; Pooidae, Chloridoideae and Panicoideae (Figure 1 and 2).

**Global Distribution**
Depending on climate and geography, grass pollens represent major contributors of airborne allergens during spring as well as summer. They grow on all continents and represent 25% to 35% of the earth’s vegetation. Pooidae dominate temperate climate zones; Chloridoideae cover the North American, African and Australian continents and Panicoideae grow in tropical and subtropical environments of Asia, Australia, Africa and South America (Figure 3).

**Allergens of Grass Pollen**
Grass pollen allergens are grouped according to their protein structure and function (Table 1). They are named according to the official nomenclature (www.allergen.org), i.e.: Phl p 1 = grass group 1 allergen from Phleum pratense (timothy grass). Ten designated groups consist of major (>50% sensitization rate, SR) and minor allergens (<50% SR). Due to their abundance and potency, grass group 1 and 5 allergens are considered immunodominant major Pooidae pollen allergens (Figure 4). While group 5 allergens are restricted to the Pooidae subfamily, group 1 allergens are present throughout the subfamilies of Poaceae. In contrast, pan-allergens profilin (group 12) and polcalcin (group 7) contribute to ubiquitous cross-reactivity between grass, tree and weed pollen in 10 – 15% of grass pollen sensitized subjects. Present concepts of homologous allergen groups, are based on similar biochemical composition, homology and immune cross-reactivity reflecting in most cases their close taxonomic relationship and have been adopted by the European Medicines Agency (EMA).

**Clinical Allergy Based on Sensitizations**
Sensitizations to grass pollen allergens, indicated by grass pollen allergen (extract) positive skin test or specific IgE, reflect regional plant distribution and pollen exposure. Population based sensitization rates are mainly available for Europe and the US and vary considerably between and within countries (Figure 5). Grass pollen allergy is a global problem (Figure 5c). At least half of grass pollen allergen sensitized subjects will suffer from symptoms of allergic rhinoconjunctivitis and/or bronchial asthma, particularly during the warm seasons in moderate climate regions.
Figure 1  Pictures of different grass species and their pollen: a - Timothy grass (*Phleum pratense*), subfamily Pooideae; b - Bermuda grass (*Cynodon dactylon*), subfamily Chloridoideae; c - Bahia grass (*Paspalum notatum*), subfamily Panicoideae.

DIAGNOSIS AND TREATMENT

Positive skin prick tests and elevated specific serum IgE to grass pollen preparations indicate allergic sensitizations, being clinically relevant only in case of corresponding symptoms. Measuring IgE to major allergens (i.e., Phl p 1 and 5) increases analytical specificity for temperate grass pollen allergy, particularly in case of sensitizations to cross-reactive pollen-panallergens. Specific immunotherapy is most successfully applied for at least three years by subcutaneous injections or sublingual home use of droplets or tablets with monopreparations of one grass species, but also grass mixes (mainly Pooidae), with or without adjuvants.

Modified from (1). Due to their taxonomic and biochemical relationship, many grasses contain similar allergens grouped according to shared amino acid sequences. Specific allergens from timothy grass (*Phleum pratense*, see middle column) are given as examples of the listed grass allergen groups.
